PRIMARY FUNCTIONS

MAPPING PROGRAM

Branch of Photogrammetry
Division of Operations
BLM - Alaska State Office

The Branch of Photogrammetry has the lead in the mapping sciences for BLM-Alaska with responsibility for applications in support of Conveyances, Cadastral Survey, Energy, Fire, and Resources. The requesting office outlines project requirements which are then used to develop design criteria, product specifications, and procedures to meet mapping needs. The types of map products include: 1) rectified and orthophotos which are distortion free and which may be composited with the rectangular land net, 2) meander line maps in the format of the rectangular survey plat and associated tabular data of upland acreage, 3) administrative/management units such as fire management plans, engineering site maps, and 4) easement identification maps.

Many mapping processes in BLM-Alaska use computer assisted techniques to meet project requirements. Photogrammetric mapping produces rectified/orthophoto products which are used by realty specialists for Native Allotment field exams, by the field surveyor when doing the rectangular survey, and in the production of meander line data for the rectangular survey plat. Photointerpretation criteria are established to provide documentation for meander line determination from aerial photos. The photointerpreted data are merged with existing field survey information and are then digitized for computer entry. These data are processed for output in the format of the rectangular plat with an upland acreage listing. The goal is to automate the production of rectangular survey plats by merging photointerpreted meander line data with rectangular or survey data using computer assisted cartography.

Other mapping support is provided by special project digitizing for Fire, District Offices and Resource Areas, resource programs, and Information Services to produce graphic and tabular data. Aerial photographic based map products are provided by the photo lab in support of map projects. Maps in support of ANCSA are of selections, easements, and navigability to be used as official documents in the conveyance process.

The Branch of Photogrammetry provides technical support through public contact service, the photo lab, and printing and reproduction services. BLM-Alaska State Office is the repository for the federal copy of the Alaska High Altitude Photography Program. This data source has been acquired through funding of a cooperative agreement among ten federal agencies and one state agency. Through this program ninety (90) percent of Alaska to date is covered with recent aerial photos.

The Mapping and Cartographic sections have expertise in manual and digital cartography. The section chiefs are responsible for project planning, workload assignments, project coordination with requesting offices and development phases. Personnel in support of the mapping program are as follows: three analytical plotter operators, four photointerpreters, four digitizers, one cartographic technician for manual mapping, four photo lab personnel, and three program support personnel.

Current Projects

1. Conveyances - Native Allotment Field Exams

The Resource Areas identify 200-300 townships per year for which rectified/-orthophoto products are needed. Aerotriangulation and digital terrain data are produced on a model by model basis for the target areas. Rectified or orthophotos are produced from these data and then composited with the land net grid based on control point registration. These 1:31,680 scale products are used by the realty specialist when visiting the parcel with the applicant. The annotated photo becomes part of the case file for future use by Cadastral Survey.

2. Conveyances - Field Survey

Cadastral Survey requests rectified/orthophoto landnet composites at 1:31,680 scale for use by the field crews when doing rectangular survey. The average annual request is for coverage of 200-300 townships. The increased emphasis on the use of these products is maintaining an identified two to three year workload for the mapping program.

3. Conveyances - Meander Line Data for Cadastral Survey

Cadastral Survey initially has requested meanderline data for 2,200 townships for rectangular survey plats using aerial photointerpretation. This meander line data project has completed 393 townships to date (May, 1984), 161 so far in FY 84. The annual production rate is 350 townships. Documentation of photointerpretation standards is based on field reconnaissance by a surveyor and photointerpreter in conjunction with guidelines from the Manual of Survey Instructions (1973) and procedural memoranda from Cadastral Survey. Photointerpreted meander line data which are registered to rectified or orthophotos are merged with the field calls from field survey. The overlays of meander lines are quality checked for completeness and consistency of photointerpretation, agreement with field survey data and platting conventions, and edge match between adjacent townships. These photointerpreted overlays are then digitized using AHDS (Alaska Hydrography Digitizing System) and processed thru MOSS (Map Overlay Statistical System) to provide map products in the format of the rectangular survey plat and tabular acreage listing by lot. (Examples of the steps and products follow.) The success of this project is attributed to strong coordination and commitment between the Division of Operations and the Division of Cadastral Survey.

4. Special Projects

Often a request is received to provide products over a small area for a special application. For example, Division of Mineral Resources requested orthophoto coverage over nine townships to use in an assessment for the location of exploratory drilling for oil reserves in the Arctic National Wildlife Reserve. Four to five requests of this type are received each year.

5. Conveyances - Digitizing Contract for Hydrography, Protraction Diagrams

A contract package has been prepared for digitizing hydrography from 1:63,360 scale USGS quadrangles to update protraction diagrams. Many of the protraction diagrams were derived from 1:250,000 scale quadrangles which were the only data source at the time. The project covers unsurveyed lands in areas of concern which have been targeted for conveyance actions in order to verify upland acreages. The product is digital hydrography for 1,000 - 2,000 township windows. The contract specifications were designed to permit the production of master title plats from the protraction data. An assessment of the results will be made for continuation of the project in the future providing funding is available.

GEOPROCESSING SECTION

Branch of Photogrammetry
Division of Operations
BLM - Alaska State Office

As BLM Alaska moves from a land transferring agency to a land management agency, the need increases for accurate resource data to implement plans and manage resources. Remote sensing and geoprocessing (RS/GIS) technologies are particularly effective in Alaska due to the large inaccessible areas and lack of background data. RS/GIS technology allows resource specialists and managers to rapidly overview an area and to concentrate on assessing and managing resources on a large scale. Resource data analysis is used to various extents in support of environmental assessments and impact statements, resource management plans, inventories of natural resources, fire fuels mapping, road suitability, corridor analysis and minerals trespass. This is an operational program which contributes significantly to BLM activities in Alaska.

BLM-Alaska has been a pioneer in the development of remote sensing and geoprocessing technology for the past ten years. An initial project with NASA on the Denali Hiway firmly established the utility of RS/GIS for Alaska. Currently, digital data bases are available for 28 million acres in the NPRA, Nulato Hills, and the Kvichak areas. An additional 8 million acres are in progress. A large project to map fire fuels for 250 million acres for the Alaska Initial Attack Management System project has recently begun. Formal and informal training, and coordination with District and Area Offices is a continuing activity.

The Geoprocessing section has expertise in manual and digital analysis, and applications of data bases. The Coordinator is responsible for program work. The Analyst works on digital projects, performing operational analysis and technical development. The Mapper is responsible for manual interpretation of remote sensing data. District and Area Office personnel integrate expertise of the area and work with the analysts during all phases of a project.

Resource geoprocessing in Alaska is primarily done on the IDIMS system at the USGS EROS Field Office. BLM provides analyst expertise and buys computer time to create and manipulate data bases. Technical developments are moving toward an integrated GIS system which incorporates the best from several software packages, including MOSS and IDIMS. Work with current projects has integrated data from several sources or systems into one data base. The GIS will use either raster or vector data sets for input and analysis, manipulate raster and vector data sets together, integrate tabular or textual data, and perform statistical analysis for a variety of output products. The next major move is to put geoprocessing capabilities in the District and Area Offices. Data bases will be developed by the State Office and then transferred to field offices for manipulation and product generation. The new MV 10000 computer will be a big asset to this distributed processing. We need to plan for terminals and plotters in field offices, and train personnel in their use. This move will greatly increase the utilization and applications of the data bases.

Current Projects

1. Kvichak digital data base - Peninsula Resource Area. This data base is being used to select lands and define stipulations for oil and gas leasing under ANILCA 1008. The main elements in the data base are landcover elevation, slope aspect, hydrography, villages and BLM lands. The landcover was borrowed from a large project by the State of Alaska, and the topo data base layers were created by DSC.

There have been several exciting developments and new applications with this data base. The topographic data were used to calculate terrain diversity, relief, and shaded relief. Combined with landcover, these images were used to interpret management units, geomorphology, and engineering restraints. Salmon streams were digitized using AHDS and processed in MOSS for transfer and incorporation in the data base. The hydrography will be used with other layers to evaluate moose, bear, and salmon habitats. Village locations and travel ranges will be merged with habitat to evaluate areas of heavy subsistence use. The next step is to incorporate ownership data from AALRS in the data base.

2. Anvik/Bonasilla digital data base - McGrath Resource Area. A data base is being prepared for use in preparation of an EA to support 1008 oil and gas leasing, and for resource management in the area.

3. Fire Fuels Mapping - Alaska Fire Service
Fire fuels are being mapped for 250 million acres of Alaska. These data are being manually interpreted from Landsat images. They will be digitized and incorporated into the Alaska Initial Attack Management System (AIAMS). The AIAMS data base will be used to make decisions on initial attack of wildfires.
